Keywords: MRS, Signal Processing, MPM.

This work aims to evaluate the applicability of the Matrix Pencil Method (MPM) algorithm for processing clinical Magnetic Resonance Spectroscopy (MRS) data.

The MPM, based on the work of Yingbo Hua and Tapan Sarkar [1], is a numerical technique for estimating signal parameters by modeling a matrix system derived from the concept of a "function pencil." A main matrix is constructed from the signal itself, where each row corresponds to the signal shifted by a fixed step difference, with the total shift length being L , which also defines the matrix size. This matrix is decomposed using the Singular Value Decomposition (SVD) method, and the least significant values of the decomposition—typically corresponding to noise—are filtered out, reconstructing the matrix with fewer elements. After reconstruction, the matrix is split into two submatrices, Y_1 and Y_2 , where the former is the main matrix without its last column and the latter is the main matrix without its first column. These two submatrices, through a pencil, then have their generalized eigenvalues computed, resulting in the poles z_i , which contain information about the frequency ω_i and decay time $T_{2,i}$. From these poles, the residues R_i are calculated by solving a least-squares problem. The residues, in turn, contain the remaining information about the amplitude $S_{0,i}$ and phase ω_i .

Using an in-house simulation based on empirical parameters of brain metabolites, synthetic MRS signals were generated and artificially corrupted with Gaussian noise, varying the Signal-to-Noise Ratio (SNR) between 1 dB and 100 dB. These corrupted signals were then post-processed using the locally implemented MPM algorithm, successfully recovering the original signal parameters: the set of amplitudes S_0 , frequencies ω , phases ϕ , and decay times T_2 .

The behavior of these parameters was analyzed for different SNR levels, revealing an important role of the amplitude S_0 in signal composition. The performance of a single peak under noise was also studied, showing an exponentially decreasing trend in the number of relevant peaks as SNR increased, with the single peak prevailing as the highest value among all.

As a next step, it is intended to investigate the behavior of signal parameters with the overlap of two peaks, thereby increasing the method's potential applicability.
